Desmoid-Type Fibromatosis in a Young Male

Fibromatose do Tipo Desmóide num Jovem

Figure 1 – T2 weighted magnetic resonance imaging of left gluteal region showing a large mass within the gluteus maximus muscle and adjacent to the sciatic nerve. Sagittal view.

A 17-year-old boy presented to our emergency department with an 8-month history of pain and swelling in the left buttock. Physical examination revealed a firm, fixed, large mass, with extension to the thigh with no inflammatory signs.

Magnetic resonance imaging (MRI) showed a mass measuring $17.1 \times 14.1 \times 10.3$ cm (Fig. 1) located deep within the gluteus maximus muscle and adjacent to the sciatic nerve. The biopsy confirmed the diagnosis of desmoid-type fibromatosis (DTF). He started chemotherapy with metronomic vinorelbine (90 mg *per* week) with stable disease.

DTF is poorly understood and rare in childhood.¹ It is a low-grade malignancy with a high potential for local recurrence. However, it does not metastasize.²-⁴ DTF is commonly seen in the extremities, abdominal wall and mesentery. The definite diagnosis is made histologically.¹ Computed tomography or MRI is needed to assess resectability. Chemotherapy is used in progressive/symptomatic cases where surgery would cause unacceptable morbidity.²
