A 59-year-old male patient presented to our hospital with right-sided renal colic. He was successfully treated with ketoprofen and the stone was spontaneously expelled. A computed tomography-scan was performed during this episode and showed the appendix extending into the right inguinal canal (Fig.s 1 and 2). The diagnosis of type I Amyand’s hernia was made fortuitously.

Amyand’s hernia is a rare occurrence where the vermiform appendix is found in an inguinal hernia sac, looking either healthy or inflammed.1 It can be an incidental finding in imaging or during surgery for incarcerated hernia.2 In the case of incidental image finding, the most accepted treatment is appendix preservation.2 When the patient undergoes surgery for incarcerated hernia, reduction and mesh repair should be done when the appendix is healthy, while appendectomy and hernia repair without using mesh should be done when the appendix is inflamed.4 Clinicians should be aware of this uncommon disease that can demand specific treatment.
